## CHEMICAL BOND

## Prepared by

Shreemoyee Phukan, Silapathar College

A chemical bond is a sort of attraction which keeps the two atoms together. Thus, depending upon the variety of force, there may be variety of chemical bonds.

## REASONS FOR THE FORMATION OF A CHEMCIAL BOND:

Energy concept: When two atoms approach each other, the attractive and repulsive forces operate between them. The distance at which the attractive forces overweigh the repulsive forces is known as the bond distance, the potential energy of the system is minimum and the bond is said to be formed.

Lewis and Langmuir: Concept of stable electronic configuration.
Atoms enter into chemical bonding to acquire the stable inert gas electronic configuration. They can do so by losing, gaining or sharing of electrons.

## TYPES OF CHEMCIAL BOND

Depending upon the mode of acquiring the stable electronic configuration, the chemical bonds may be
Ionic or electrovalent bond
Covalent bond
Coordinate or dative bond
Metallic bond
Hydrogen bond
Weak van der Waals forces of attraction

## IONIC BOND

Ionic bond is formed by the complete transference of one or more valence electrons of one atom to the valence shell of the other atom. Both atoms are converted into ions and have the electronic configuration of nearest noble gases. The ions, which always tends to decrease the potential energy of the system is known as the ionic bond. Consider the formation of KCl . The electronic configuration of $\mathrm{K}, \mathrm{Cl}$ and their ions ( $\mathrm{K}+$ and $\mathrm{Cl}-$ ) are given below

K (19): $1 s^{2} 2 s^{2} 2 p^{6} 3 s^{2} 3 p^{6} 4 s^{1}$
$\mathrm{K}+(18): 1 \mathrm{~s}^{2} 2 \mathrm{~s}^{2} 2 \mathrm{p}^{6} 3 \mathrm{~s}^{2} 3 \mathrm{p}^{6}$ Inert gas (Ar) configuration
Cl (17): $1 \mathrm{~s}^{2} 2 \mathrm{~s}^{2} 2 \mathrm{p}^{6} 3 \mathrm{~s}^{2} 3 \mathrm{p}^{5}$
$\mathrm{Cl}(18): 1 \mathrm{~s}^{2} 2 \mathrm{~s}^{2} 2 \mathrm{p}^{6} 3 \mathrm{~s}^{2} 3 \mathrm{p}^{6}$ Inert gas (Ar) configuration
$\mathrm{K}^{+}+\mathrm{Cl}^{-}=\mathrm{KCl}$
The number of electrons lost or gained by an atom represents the electrovalency of the atom.

## FAJAN'S RULE:

This rule is for covalent character of an ionic bond. Covalent character of an ionic bond is favoured by
Smaller positive ion
(ii) Large negative ion
(iii) Large charge on ions

Thus for a fixed cation, the larger the size of anion, the more the magnitude of the charge, the more is covalent character eg. Covalent character of sodium halides follows the order.

$$
\mathrm{NaI}>\mathrm{NaBr}>\mathrm{NaCl}>\mathrm{NaF}
$$

For fixed anion, the smaller the size of cation, the more the magnitude of the charge, the more is the covalent character.

Eg. $\quad \mathrm{BeCl}_{2}>\mathrm{MgCl}_{2}>\mathrm{CaCl}_{2}>\mathrm{SrCl}_{2}>\mathrm{BaCl}_{2}$
It has been observed that a cation having $18\left(s^{2} \mathrm{p}^{6} \mathrm{~d}^{10}\right)$ electrons in outermost shell (pseudo noble gas configuration) can polarize the anion more than cation having $8\left(s^{2} \mathrm{p}^{6}\right)$ noble gas electronic configurations. Hence CuCl is more covalent than NaCl . Similarly AgCl is more covalent that KCl .

## POLARISING POWER OF CATION :

The power of cation to attract the electron cloud toward itself is called polarizing power of cation.

## POLARISATION:

When cation and anion come closer to each other, the electron could of anion is attracted towards the cation; some partial sharing of electrons take place, the anion is distorted and the effect is known as polarisation.
*More the effect of polarisation, more is the sharing of electrons and the more is covalent character of ionic bond.

## COVALENT BOND:

According to G.N. Lewis, atoms may also combine by sharing of electrons in their outermost shells and attain noble gas electronic configuration. One shared pair of electrons constitute a single bond, two electron pairs constitute a double bond so on. The bonds thus formed are known as covalent bonds.

COVALENCY:

It is the number of electron pairs shared by one atom of the element in combination with other atoms in a molecule. It can also be defined as the number of covalent bonds formed by the atom of the element with other atoms.

## Variable Covalency:

Generally the covalency of an element is equal to the total number of unpaired electrons in s and p orbitals of the valence shell. For example
${ }^{6} \mathrm{C}=1 \mathrm{~s}^{2}, 2 \mathrm{~s}^{1}, 2 \mathrm{p}_{\mathrm{x}}{ }^{1}, 2 \mathrm{p}_{\mathrm{y}}{ }^{1}, 2 \mathrm{p}_{\mathrm{z}}{ }^{1} \quad$ Covalency of carbon $=4$
${ }^{8} \mathrm{O}=1 \mathrm{~s}^{2}, 2 \mathrm{~s}^{2}, 2 \mathrm{p}_{\mathrm{x}}{ }^{2}, 2 \mathrm{p}_{\mathrm{y}}{ }^{1}, 2 \mathrm{p}_{\mathrm{z}}{ }^{1} \quad$ Covalency of oxygen $=2$

* The variable covalency is shown by elements having vacant d-orbitals in their valence shell. The unpairing of the $s$ and $p$ electrons is possible by promoting them to $d$-orbitals. For example

$$
\begin{gathered}
{ }^{16} \mathrm{~S}=1 \mathrm{~s}^{2}, 2 \mathrm{~s}^{2}, 2 \mathrm{p}^{6}, 3 \mathrm{~s}^{2}, 3 \mathrm{p}_{\mathrm{x}}{ }^{2}, 3 \mathrm{p}_{\mathrm{y}}{ }^{1}, 3 \mathrm{p}_{\mathrm{z}}{ }^{1} \quad \text { Covalency of sulphur }=2 \\
=3 \mathrm{~s}^{2}, 3 \mathrm{p}_{\mathrm{x}}{ }^{1}, 3 \mathrm{p}_{\mathrm{y}}{ }^{1}, 3 \mathrm{p}_{\mathrm{z}}{ }^{1}, 3 \mathrm{~d}_{\mathrm{xy}}{ }^{1}
\end{gathered}
$$

First excited state $\quad$ covalency of sulphur $=4$

$$
=3 \mathrm{~s}^{1}, 3 \mathrm{p}_{\mathrm{x}}{ }^{1}, 3 \mathrm{p}_{\mathrm{y}}{ }^{1}, 3 \mathrm{p}_{\mathrm{z}}{ }^{1}, 3 \mathrm{~d}_{\mathrm{xy}}{ }^{1}, 3 \mathrm{~d}_{\mathrm{yz}}{ }^{1}
$$

Second excited state covalency of Sulphur $=6$
Similarly, other than fluorine, the halogens have high covalencies equal to 3,5 and 7. Phosphorous shows covalencies equal to 3 and 5 .

The elements having no d-orbitals do not exhibit variable covalency.

## NATURE OF COVALENT BOND

The nature of covalent bond is explained by
$>$ Heitler - london theory
> Pauling - slater theory
$>$ Hund - mulliken theory
$>$ Valence bond theory
> Molecular orbital theory
VALENCE BOND THEORY: This theory is given by Heiteler and London, to explain how a covalent bond is formed. This theory is explained by a Slater, the main points of this theory are;

A covalent bond is formed by the overlapping between two half filled atomic orbitals having electrons with opposite spin.

The atom with half fill atomic orbitals comes closer to one another at a proper axis.
As a result of overlapping, there is maximum electron density between the two atoms.
Greater the overlapping, higher is the strength of chemical bond.
Two types of bonds are formed on account of overlapping. These are-
(a) Sigma bond ( $\sigma$ ) and (b) Pi bond (л).

Sigma bond ( $\sigma$ bond) - This type of covalent bond is formed by the end to end overlapping of orbitals along the inter-nuclear axis. The overlap is known as head on overlap or axial overlap. The following overlapping result in the formation of sigma bond.
$\mathrm{s}-\mathrm{s}$ overlapping (Formation of Hydrogen Molecule)
$\mathrm{s}-\mathrm{p}$ overlapping (Formation of $\mathrm{HF}, \mathrm{HCl}$ Molecules)
$\mathrm{p}-\mathrm{p}$ head on overlapping (Formation of $\mathrm{F}_{2}, \mathrm{Cl}_{2}$ Molecules)
Bond between two hybrid orbitals $\mathrm{sp}^{3}-\mathrm{sp}^{3}, \mathrm{sp}^{2}-\mathrm{sp}^{2}, \mathrm{sp}^{3}-\mathrm{sp}^{2}, \mathrm{sp}^{3}-\mathrm{sp}, \mathrm{sp}^{2}-\mathrm{sp}, \mathrm{sp}-\mathrm{sp}$ etc. overlapping of orbitals form $\sigma$ bond.
pi - bond (л - bond) - It is formed by the sidewise or lateral overlapping between unhybridised p atomic orbitals. The orbitals involved in side wise overlap must be parallel and perpendicular to the internuclear axis. It is always accompanied by a $\sigma$ bond and consist of two charge clouds i.e. above and below the plane of sigma bond.

Since overlapping take place on both sides of the inter-nuclear axis free rotation of atoms around a pi bond is not possible.

- $\quad$ bond is a weaker bond than $\sigma$ - bond.

The strength of $\sigma$-bond depends upon the extent of overlapping between atomic orbitals. Greater the overlapping stronger is the $\sigma$-bond. It follows the following order

- $\mathrm{s}-\mathrm{s}>\mathrm{s}-\mathrm{p}>\mathrm{p}-\mathrm{p}$
- Single bond is always $\sigma$ - bond.
- In multiple bonds only one is $\sigma$ bond, others are л-bonds.
- л-bond is not formed by hybrid orbitals.

## LIMITATIONS OF VALENCE BOND THOERY:

- It fails to explain the magnetic properties of some molecules.
- Bonding in electron deficient compounds.
- It could not define the formation of $\mathrm{H} 2+$
- It could not explain the paramagnetic character O2.
- It could not explain the formation of Coordinate bond.
- It could not explain the Fazan's Rule.

## Differences between Valnce Bond Theory (VBT) and Molecular Orbital Theory(MOT)

|  | Molecular Orbital Theory |
| :---: | :---: |
| 1. Electrons in the molecule are localized as if they are in isolated atoms. <br> 2. The atomic orbitals of the combining atoms retain their individual identity to large extent. <br> 3. It takes into account only the increase in the electron density in the region of orbital overlap. <br> 4. The number of covalent bonds formed is equal to half of the number of combining atomic orbitals. <br> 5. It does not predict the paramagnetic or diamagnetic behavior of molecules or ions. <br> 6. It is quite easy to apply. <br> 7. Resonance has an important role in this theory. | It regards the nuclei of the molecules as polycentric and then constructs the molecule. <br> The atomic orbitals of the combining atoms lose their individual identity in the molecular orbitals. <br> It takes into account the increase as well as decrease in electron density in the region of orbital overlap. <br> The number of bonds (or bond order) is half the difference in the bonding and antibonding electrons. <br> It can predict the paramagnetic and diamagnetic behavior of molecules or ions. <br> It is rather difficult to apply. <br> Resonance has no role in this theory. |

## MOLECULAR ORBITAL THEORY OR HUND-MULLIKEN THEORY:

According to this theory the atomic orbitals combine to form the molecular orbitals. The number of molecular orbitals formed is equal to the number of atomic orbitals involved and they belong to the molecule.

The molecular orbitals are formed by LCAO method (linear combination of atomic orbitals) i.e. by addition or subtraction of wave functions of individual orbitals thus

Molecular orbital of lower energy is known as bonding molecular orbital and of higher energy is known as antibonding molecular orbital.

Molecular orbitals are characterized by a set of quantum numbers.
Bond order- It is defined as one half the difference between the number of electrons present in the bonding and the antibonding orbitals.
i.e. Bond order (b.o) $=1 / 2\left(N_{b}-N_{a}\right)$. where, $N_{b}=$ no. of bonding electrons
$\mathrm{N}_{\mathrm{a}}=$ no. of antibonding electrons

## Stability of molecule- bond order.

The bond order of 1, 2 and 3 corresponds to single, double and triple bond respectively. It may be mentioned that according to M. O. theory, even a fractional bond order is possible.

Magnetic property - If all the elements in a molecule are paired then substance is diamagnetic, on the other hand if there are unpaired electrons in the molecule the substance is paramagnetic. More the number of unpaired electrons in the molecule greater is the paramagnetism of the substance.

## ELECTRONIC CONFIGURATION/ BOND ORDER OF SIMPLE DIATOMIC MOLECULES:

The electronic configuration and the bond order in case of simple diatomic molecules can be obtained by filling the molecular orbitals by applying Aufbau principle and Hunds rule. The increasing order of energies of various molecular orbitals upto $\mathrm{N}_{2}$ molecule is

$$
\sigma_{1 \mathrm{~s}}<\sigma_{1 \mathrm{~s}} *<\sigma_{2 \mathrm{~s}}<\sigma_{2 \mathrm{~s}} *<\left(\Pi_{2 \mathrm{px}}=\pi_{2 \mathrm{py}}\right)<\sigma_{2 \mathrm{pz}}<\left(\Pi_{2 \mathrm{px}} *=\pi_{2 \mathrm{py}} *\right)<\sigma_{2 \mathrm{pz}} *
$$

For $\mathrm{O}_{2}$ and $\mathrm{F}_{2}$ is given below

$$
\sigma_{1 \mathrm{~s}}<\sigma_{1 \mathrm{~s}} *<\sigma_{2 \mathrm{~s}}<\sigma_{2 \mathrm{~s}} *<\sigma_{2 \mathrm{pz}}<\left(\pi_{2 \mathrm{px}}=\pi_{2 \mathrm{py}}\right)<\left(\pi_{2 \mathrm{px}} *=\pi_{2 \mathrm{py}} *\right)<\sigma_{2 \mathrm{pz}} *
$$

| $\begin{aligned} & \text { SI. } \\ & \text { No } \end{aligned}$ | Molecule/ ion | No. of electrons | Electronic Configuration | Bond Order $1 / 2\left(N_{b}-N_{a}\right)$ | Magnetic Property |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{H}_{2}$ | 2 | $(\sigma 1 \mathrm{~s})^{2}$ | $1 / 2(2-0)=1$ | Diamagnetic |
| 2 | $\mathrm{H}_{2}{ }^{+}$ | 1 | $(\sigma 1 \mathrm{~s})^{1}$ | $1 / 2(1-0)=1 / 2$ | Paramagnetic |

## HYBRIDISATION:

Hybridisation is the redistribution of energy levels at the time of formation of molecules. It may also be defined as intermixing of atomic orbitals of nearly the same energy and resulting in the formation of new atomic orbitals same in number and identical in all respects (shape, energy and size). The new atomic orbitals are known as hybrid atomic orbitals.

The completely filled or half filled atomic orbitals can take part in hybridization and hybrid atomic orbitals form stronger bonds.
$\mathbf{s p}^{3}$ Hybridization. If one s and three p -orbitals are intermixed or hybridized, this is known as sp 3 -hybridization. Four equivalent orbitals will be formed which are called $\mathrm{sp}^{3}$ hybridized orbitals which are directed along the four corners of a tetrahedron with bond angle $109^{\circ} 28^{\prime}$, e.g., in $\mathrm{CH}_{4}$, carbon undergoes $\mathrm{sp}^{3}$ hybridization and it has tetrahedral shape.
$\mathbf{s p}^{\mathbf{3}} \mathbf{d}$ Hybridisation. When one s , three p and one d-orbitals intermix together and give rise to five $\mathrm{sp}^{3} \mathrm{~d}$ hybridized orbitals. The shape of molecule is trigonal bipyramidal. Bond angle is $90^{\circ}, 120^{\circ}$, e.g., $\mathrm{PF}_{5}, \mathrm{PCl}_{5}$ involves $\mathrm{sp}^{3} \mathrm{~d}$ hybridization.
$\mathrm{sp}^{3} \mathrm{~d}^{2}$ Hybridisation. When one s , three p and two d-orbitals intermix to give rise to six $\mathrm{sp}^{3} \mathrm{~d}^{2}$ hybridised orbitals. The shape of molecule having $\mathrm{sp}^{3} \mathrm{~d}^{2}$ hybridisation will be octahedral with bond angle $90^{\circ}$, e.g., $\mathrm{SF}_{6}$, involve $\mathrm{sp}^{3} \mathrm{~d}^{2}$ hybridisation and possess octahedral shape.
$\mathbf{s p}^{\mathbf{2}}$ Hybridisation. If one s and two p -orbitals are intermixed, it is called $\mathrm{sp}^{2}$-hybridization. Three equivalent orbitals are called sp 2 hybridized orbitals which will be directly along the corners of equilateral triangle having bond angle $120^{\circ}$, e.g., in $\mathrm{BF}_{3}$, ' B ' atom undergoes $\mathrm{sp}^{2}$ hybridization and its shape is a planar.
sp Hybridisation. If one s and one p orbital intermix, it is called sp-hybridization. The two sp hybridized orbitals are far-apart. In $\mathrm{BeF}_{2}, \mathrm{Be}$ atom undergoes sp-hybridization and it has linear shape with bond angle $180^{\circ}$.

## Hybridisation in some important molecules.

$\mathrm{CH}_{4}$ molecule. $\mathrm{C}(6)$ has electronic configuration in ground state $1 s^{2} 2 s^{2} 2 p_{x}{ }^{1} 2 p_{y}{ }^{1} 2 p_{z}{ }^{0} \mathrm{C}$ (6) in excited state $1 s^{2} 2 s^{1} 2 p_{x}{ }^{1} 2 p_{y}{ }^{1} 2 p_{z}{ }^{1}$ (since carbon is tetravalent we need excited state).

sp3 hybridization

- $\mathrm{NH}_{3}$ molecule. $\mathrm{N}(7) 1 \mathrm{~s}^{2} 2 s^{2} 2 p_{x}{ }^{1} 2 p_{y}{ }^{1} 2 p_{z}{ }^{1}$ (since nitrogen is trivalent we do not need excited state).

$\mathrm{sp}^{3}$ - Hybridisation.
- $\mathbf{H}_{\mathbf{2}} \mathbf{O}$ molecule. O (8) $1 \mathrm{~s}^{2} 2 \mathrm{~s}^{2} 2 p_{\mathrm{x}}{ }^{2} 2 p_{\mathrm{y}}{ }^{1} 2 \mathrm{p}_{\mathrm{z}}{ }^{1}$ (since oxygen is divalent, we do not need excited state).
$2 S \quad 2 p$

(i) $\mathbf{s p}^{2}$ - Hybridisation.
$B F_{3}$ molecule. $B(5) 1 s^{2} 2 s^{2} 2 p_{x}{ }^{1}$ in ground state
$B(5): 1 s^{2} 2 s^{1} 2 p_{x}{ }^{1} 2 p_{y}{ }^{1} 2 p_{z}{ }^{0}$ in excited state (since boron is trivalent only in excited state).
$>\quad \mathrm{Sp}^{2}$ hybridization
METHOD FOR FINDING THE TYPE OF HYBRIDISATION:
Apply the following formula to find the hybridization of central atom.

$$
\frac{1}{2}\left(\begin{array}{c}
\text { number of valence electrons of central atom } \\
+ \text { number of monovalent atoms attached to it } \\
+ \text { negative charge if any - positive charge if any }
\end{array}\right)=z
$$

| Value of $z$ | 2 | 3 | 4 | 5 | 6 | 7 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Hybridisation | sp | $\mathrm{sp}^{2}$ | $\mathrm{sp}^{3}$ | $\mathrm{sp}^{3} \mathrm{~d}$ | $\mathrm{sp}^{3} \mathrm{~d}^{2}$ | $\mathrm{sp}^{3} \mathrm{~d}^{3}$ |

## Examples:

i) Hybridisation of $\mathrm{NH}_{3}=\frac{1}{2}[5+3+0-0]=4$; $\mathrm{sp}^{3}$
ii) Hybridisation of $\mathrm{H}_{2} \mathrm{O}=\frac{1}{2}[6+2+0-0]=4$; $\mathrm{sp}^{3}$
iii) Hybridisation of $\mathrm{SO}_{3}=\frac{1}{2}[6+0+0-0]=3$; $\mathrm{sp}^{3}$
iv) Hybridisation of $\mathrm{SO}_{4}^{2-}=\frac{1}{2}[6+0+2-0]=4 ; \mathrm{sp}^{3}$
v) Hybridisation of $\mathrm{CO}_{3}^{2-}=\frac{1}{2}[4+0+2-0]=3 ; \mathrm{sp}^{2}$
vi) Hybridisation of $\mathrm{PCl}_{3}=\frac{1}{2}[5+5+0-0]=5 ; \mathrm{sp}^{3} \mathrm{~d}$

Hybridisation of $\mathrm{SF}_{6}=\frac{1}{2}[6+6+0-0]=6 ; \mathrm{sp}^{3} \mathrm{~d}^{2}$

## Polar And Non Polar Covalent Bonds:

If the two bonded atoms have equal values of electronegativites, the bonded pair of electrons is equally shared between them, i.e. shared pair of electrons remains in the middle (just in between the atoms). Such a bond is called non polar covalent bond.

For example $\mathrm{H}-\mathrm{H}, \mathrm{O}=\mathrm{O}, \mathrm{N}=\mathrm{N}, \mathrm{C}-\mathrm{C}, \mathrm{F}-\mathrm{F} \ldots$ $\qquad$ .etc bonds. However, if the bonded atoms differ in their electronegativites, the bonded paired of electron is attracted more towards atom with the larger electronegativity, resulting in the development of partial negative charge over this atom and equal but opposite charge over the other bonded atom. Such a covalent bond is called Polar covalent bond.

For e.g. $\mathrm{I}-\mathrm{Cl}, \mathrm{C}-\mathrm{Cl}, \mathrm{C}=\mathrm{O}, \mathrm{H}-\mathrm{F}, \mathrm{H}-\mathrm{Cl}$ etc.

$$
\mathrm{H}-\mathrm{H} \quad \mathrm{H}^{\sigma^{+}}-\mathrm{F}^{\sigma-}
$$

(non polar molecules) (polar molecule)
Extent of polarity in a bond is measured in terms of dipole moment.
Dipole Moment $(\mu)$ : It can be defined as the product of the magnitude of the charge and the distance between the centres of positive and negate e charge. It is usually designed by a Greek letter ' $\square$. Mathematically, it is expressed as follows:

Dipole moment $(\mu)=$ charge $(Q) x$ distance of separation (r).

Dipole moment is usually expressed in Debye units (D). The conversion factor is

$$
1 \mathrm{D}=3.33564 \times 10^{-30} \mathrm{~cm}
$$

Where C is coulomb and m is meter.
Further dipole moment is a vector quantity and is depicted by a small arrow with tail on the positive centre and head pointing towards the negative centre. For example the dipole moment of HF may be represented as:

$$
\xrightarrow{\mathrm{H}^{\delta+} \longrightarrow \mathrm{F}^{\delta-}}
$$

The shift in electron density is symbolised by crossed arrow $(\longrightarrow)$ above the Lewis structure to indicate the direction of the shift.

## Co-ordinate Covalent Bond or Dative Bond:

When both the electrons for sharing between two atoms are contributed by one atom only the bond formed is known as coordinate bond or dative bond.

In terms of orbital theory the co-ordinate covalent bond is formed by overlapping between empty and completely filled atomic orbitals.

The atom donating the pair of electrons is called donor and the atom which accepts the pair of electrons is called acceptor. The compound containing coordinate bonds are known as
co-ordination compounds. The bond is represented by an arrow ( $\longrightarrow$ ) pointing head towards the acceptor.
Once the coordinate bond is formed it is indistinguishable from a covalent bond.
E.g.

## CHARACTERISTICS OF CO-ORDINATE COMPOUNDS:

Co-ordinate compounds have volatile character in between ionic and covalent compounds. Other properties like solubility, electrical conductivity and stereo isomerism are similar to covalent compounds.

## HYDROGEN BOND:

It may be defined as the force of attraction existing between hydrogen atom covalently bonded to highly electronegative atom ( $\mathrm{N}, \mathrm{O}$ or F ) and the electro negative atom belonging to another molecule of the same or different substance. It is represented by dotted lines (........).

Hydrogen bond is purely electrostatic in nature. It is a weak bond, the strength of the strongest being about $5-10$ kcal per mole. The more the electronegativity of atom involved in $\mathrm{H}-$ bonding, the more is the bond strength
e.g.,
H...F > H...O > H...N
$10 \mathrm{kcal} / \mathrm{mole}>7 \mathrm{kcal} / \mathrm{mole}>2.0 \mathrm{kcal} / \mathrm{mole}$
Types of hydrogen bonds - Hydrogen bond is of two types
Intermolecular H-bonding (Association). It is formed between two different molecules of the same of different substances. For example

HF

$$
H-F \ldots \ldots . H-F \ldots \ldots . H-F
$$

$\mathrm{H}_{2} \mathrm{O}$

Alcohol in water

## Intramolecular H-bonding (chelation).

H - bonding taking place within single molecule.

(Ortho nitro phenol)

## Applications of intermolecular H - bonding.

Water has the lowest molecular weight among the hydrides of group 6 elements yet it has the highest melting and boiling points

|  | $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{H}_{2} \mathrm{~S}$ | $\mathrm{H}_{2} \mathrm{Se}$ | $\mathrm{H}_{2} \mathrm{Te}$ |
| :--- | :---: | :--- | :--- | :--- |
| Melting point | $0^{\circ} \mathrm{C}$ | $-85.5^{\circ} \mathrm{C}$ | $-66^{\circ} \mathrm{C}$ | $-51.2^{\circ} \mathrm{C}$ |
| Boiling point | $100^{\circ} \mathrm{C}$ | $-60.4^{\circ} \mathrm{C}$ | $-41.5^{\circ} \mathrm{C}$ | $+2^{\circ} \mathrm{C}$ |

It is due to intermolecular H - bonding through which water molecules associate
(b)Ice has less density than water - In crystal structure of ice every water molecule is associated with four other water molecules by $\mathrm{H}-$ bonding in a tetrahedral fashion.

It gives rise to cage likes tetrahedral structure of ice with large empty spaces. On melting the ice $\mathrm{H}-$ bonds are broken and space between water molecules decreases and density of water increases upto $4^{\circ} \mathrm{C}$. Above $4^{\circ} \mathrm{C}$ more H - bonds are broken, the water molecules move apart from each other and the density again decreases. Thus water has maximum density at $4^{\circ} \mathrm{C}$.
(c) Alcohols - The marked difference between the melting and boiling points of alcohols and corresponding mercaptans is also due to association.

|  | $\mathrm{CH}_{3} \mathrm{OH}$ | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ | $\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{OH}$ | $\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}$ |
| :--- | :--- | :--- | :--- | :--- |
| Boiling point | $64.4^{\circ} \mathrm{C}$ | $78^{\circ} \mathrm{C}$ | $97^{\circ} \mathrm{C}$ | $117^{\circ} \mathrm{C}$ |
|  | $\mathrm{CH}_{3} \mathrm{SH}$ | $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{SH}$ | $\mathrm{C}_{3} \mathrm{H}_{7} \mathrm{SH}$ | $\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{SH}$ |
| Boiling point | $5.8^{\circ} \mathrm{C}$ | $37^{\circ} \mathrm{C}$ | $67^{\circ} \mathrm{C}$ | $97^{\circ} \mathrm{C}$ |

## OCTET RULE:

During formation of a covalent bond, the atoms attain an inert gas electronic configuration (ns2p6 configuration). This is known as Octet rule. There are exceptions of octet rule.

Incomplete octet: Examples are $\mathrm{LiCl}, \mathrm{BeH}_{2}$ and $\mathrm{BCl}_{3}$.
Odd-electron molecules: E.g. $\mathrm{NO}, \mathrm{NO}_{2}$
Expanded octet: E.g. $\mathrm{PF}_{5}, \mathrm{SF}_{6}, \mathrm{H}_{2} \mathrm{SO}_{4}$

According to this theory, the bonding and non-bonding electron pairs in the valency shell of the central atom arrange themselves in such a manner that there is minimum repulsion between them. Hence, electron pair orbitals adopt arrangements in space that provide maximum separation among electron pairs.

Following rules should be followed to determine shape of the molecule and bond angle between the atoms:

The molecule which has only bond pair of electrons has definite structure, which provide maximum distance between the bond pairs.

| Number <br> of bond <br> pairs | Geometrical <br> distribution <br> of bond pairs | VSEPR <br> notation | Molecular <br> geometry | Bond <br> angle | hybridisation | Example |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 2 | Linear | $\mathrm{AB}_{2}$ | Linear | $180^{\circ}$ | sp | $\mathrm{BeCl}_{2}$ |
| 3 | Trigonal <br> planar | $\mathrm{AB}_{3}$ | Trigonal <br> planar | $120^{\circ}$ | $\mathrm{sp}^{2}$ | $\mathrm{BCl}_{3}$ |
| 4 | Tetrahedral | $\mathrm{AB}_{4}$ | Tetrahedral | $109.5^{\circ}$ | $\mathrm{sp}^{3}$ | $\mathrm{CCl}_{4}$ |
| 5 | Trigonal <br> bipyramidal | $\mathrm{AB}_{5}$ | Trigonal <br> bipyramidal | $90^{\circ}$, <br> $120^{\circ}$ | $\mathrm{sp}^{3} \mathrm{~d}$ | PCl |
| 6 | Octahedral | $\mathrm{AB}_{6}$ | Octahedral | $90^{\circ}$ | $\mathrm{sp}^{3} \mathrm{~d}^{2}$ | $\mathrm{SF}_{6}$ |
| 7 | Pentagonal <br> bipyramidal | $\mathrm{AB}_{7}$ | Pentagonal <br> bipyramidal | $90^{\circ}, 72^{\circ}$ | $\mathrm{sp}^{3} \mathrm{~d}^{3}$ | $\mathrm{IF}_{7}$ |

(i) The molecule which has bond pair as well as lone pair of electrons, do not have a definite structure.
(ii) More is the lone pair of electrons, more will be the repulsion and lesser will be the bond angle.

| (iii) Example: | $\mathrm{CH}_{4}$ | $\mathrm{NH}_{3}$ | $\mathrm{H}_{2} \mathrm{O}$ |
| :--- | :---: | :--- | :---: |
| Lone pair of electron(s) | 0 | 1 | 2 |
| Bond angle | $109^{\circ} 28^{\prime}$ | $107^{\circ}$ | 104.5 |
| Repulsion | $\mathrm{bp}-\mathrm{bp}<\mathrm{bp}-\mathrm{lp}<\mathrm{lp}-\mathrm{lp}$ |  |  |

lone pair of electrons will distort the geometry of the molecules.

| Molecule <br> type | No. of <br> bonding <br> pairs | No. of <br> lone <br> pairs | Arrangement <br> of electron <br> pairs | Shape | Hybridization | Examples |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{AB}_{2} \mathrm{E}$ | 2 | 1 | $\mathrm{AB}_{2}$ | Bent | $\mathrm{sp}^{2}$ | $\mathrm{SO}_{2}, \mathrm{O}_{3}$ |
| $\mathrm{AB}_{3} \mathrm{E}$ | 3 | 1 | $\mathrm{AB}_{3} \mathrm{E}$ | Trigonal <br> pyramidal | $\mathrm{sp}^{3}$ | $\mathrm{NH}_{3}$ |

| $\mathrm{AB}_{2} \mathrm{E}_{2}$ | 2 | 2 | $\mathrm{AB}_{2} \mathrm{E}_{2}$ | Bent | $\mathrm{sp}^{3}$ | $\mathrm{H}_{2} \mathrm{O}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{AB}_{4} \mathrm{E}$ | 4 | 1 | $\mathrm{AB}_{4} \mathrm{E}$ | See saw | $\mathrm{sp}^{3} \mathrm{~d}$ | $\mathrm{SF}_{4}$ |
| $\mathrm{AB}_{3} \mathrm{E}_{2}$ | 3 | 2 | $\mathrm{AB}_{3} \mathrm{E}_{2}$ | T-shape | $\mathrm{sp}^{3} \mathrm{~d}$ | $\mathrm{ClF}_{3}$ |
| $\mathrm{AB}_{5} \mathrm{E}$ | 5 | 1 | $\mathrm{AB}_{5} \mathrm{E}$ | Square <br> pyramid | $\mathrm{sp}^{3} \mathrm{~d}^{2}$ | $\mathrm{BrF}_{5}$ |
| $\mathrm{AB}_{4} \mathrm{E}_{2}$ | 4 | 2 | $\mathrm{AB}_{4} \mathrm{E}_{2}$ | Square <br> planar | $\mathrm{sp}^{3} \mathrm{~d}^{2}$ | $\mathrm{XeF}_{4}$ |

## RESONANCE

In this case of some of the molecules, all of their properties can't be explained by a single structure. The molecule can be represented by two or more structures. These structures are called canonical forms. The molecule is said to be resonance hybrid of all these structures. These structures have no physical reality in the sense that they cannot be prepared in the laboratory. They exist in imagination. This phenomenon of existing in more than one structure is called resonance, e.g.,

Structures I and II are resonating structure of Benzene and structure III is resonance hybrid of benzene.

## RESONANCE ENERGY

It is defined as difference in energy of actual structure of compound and most stable resonating structure, e.g., benzene has resonance energy $150.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$ or $36 \mathrm{kcal} \mathrm{mol}^{-1}$

Note: Draw the resonating structure of the following molecules.

$$
\mathrm{CO}_{2}, \mathrm{CO}_{3}^{2-}, \mathrm{O}_{3}
$$

## Some Important Terms

Lewis structure: Lewis postulated that atoms achieved the stable octet when they were linked by chemical bond. Lewis gave a symbol to denote the valence shell electrons in an atom. The outer shell electrons are shown as dots, surrounding the symbol of the element. It is also known as electron dot symbol. It does not show inner shell electrons.

Example, Na , •C•
Lattice Enthalpy
The Lattice Enthalpy of an ionic solid is defined as the energy required to completely separating one mole of a solid ionic compound into gaseous constituent ions. For example, the lattice enthalpy of NaCl is 788
$\mathrm{kJ} \mathrm{mol}^{-1}$. This means that 788 kJ of energy is required to separate one mole of solid NaCl into one mole of $\mathrm{Na}^{+}(\mathrm{g})$ and one mole of $\mathrm{Cl}^{-}(\mathrm{g})$ to an infinite distance.

## BOND LENGTH

Bond length is defined as the equilibrium distance between the nuclei of two bonded atoms in a molecule. Bond lengths are measured by spectroscopic, X-ray diffraction and electron-diffraction techniques.

It is expressed in angstrom ( $\AA$ ) units ( $1 \AA=10^{-8} \mathrm{~cm}=10^{-10} \mathrm{~m}$ or pm [(picometer) $1 \mathrm{pm}=10^{-12} \mathrm{~m}$ ).
In ionic bonds, bond length between two bonded atom is obtained by adding up their ionic radii. The covalent radius is measured approximately as the radius of an atom's core which is in contact with the core of an adjacent atom in a bonded situation. The van der Waals radius represents the overall size of the atom which includes its valence shell in a non-bonded situation.

## BOND ANGLE

It is defined as the angle between the orbitals containing bonding electron pairs around the central atom in a molecule/ complex ion. Bond angle is expressed in degree which can be experimentally determined by spectroscopic methods. It gives some idea regarding the distribution of orbitals around the central atom in a molecule/ complex ion and hence it helps us in determining its shape. For example $\mathrm{H}-\mathrm{O}-\mathrm{H}$ bond angle in water is $104.5^{\circ}$.

## BOND ENTHALPY

It is defined as the amount of energy required to break one mole of bonds of a particular type between two atoms in a gaseous state. The unit of bond enthalpy is $\mathrm{kJ} \mathrm{mol}^{-1}$. For example, the $\mathrm{H}-\mathrm{H}$ bond enthalpy in hydrogen is $435.8 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

## BOND ORDER

Bond order is the number of bonds between the two atoms in a molecule. For example, in $\mathrm{H}_{2}$ the bond order is 1 since it has single shared electron.
